

AI Usage Note

Project: StockFlow WMS (warehouse management system) | Author: Sumit Meena

My role: direction, decisions and delivery

- **Problem and scope:** I defined what to build and kept it to the core warehouse flow: receive stock into bins, reserve it when an order is confirmed, walk a pick list, then ship. I chose to solve one problem well: never promise stock that is not available.
- **Course correction:** I first asked for a copy of an existing public GitHub project. When it turned out to have no license, I changed course and had an original application built instead, under my own MIT license.
- **Setup and delivery:** I set up my own environment, fixed Git and PATH problems, created my GitHub repository, published the code, and deployed the app to a public URL on Render.
- **Demo data:** I asked for sample data covering every order status, so each step of the flow can be shown, and I pushed it to GitHub and redeployed the live site.
- **Testing and explanation:** I run the app end to end and explain how it works in my video walkthrough.

Which AI tools I used, and how

I used **Claude Code** (Claude Sonnet 5.5) in the Claude desktop app, working directly in my project folder. I used it as a pair programmer that I directed:

- **Code generation:** Given my requirements, Claude proposed the stack (React + Vite, Express, Prisma with SQLite, JWT login with admin and picker roles) and generated the code: data model, API, stock allocation logic and UI. Most of the code was written by the AI.
- **Verification:** Claude wrote unit tests for the allocation logic (4 passing), typechecked and built the app, and ran a full order through the API to confirm stock is reserved and deducted correctly.
- **Follow-ups:** I used it for Git troubleshooting, for making the app deployable as a single service, and for a seed script that loads realistic demo data (10 products, 8 bins, and 7 sample orders, one in each status) so the app can be shown without typing data in by hand.

Moments where I disagreed with or changed an AI suggestion

- **Copying an existing project:** The AI declined my request to replicate a public project and remove the author's name, because an unlicensed repository is protected by default and removing attribution would infringe it. I agreed and changed direction. The AI only saw that project's README summary; none of its code was copied.
- **Scope and hosting:** I kept to the smallest feature set that shows the full flow, and to SQLite, so the app runs locally with only Node installed and the core logic stays easy to test and explain.

Known limits

- On a free host the SQLite data resets on restart, and the demo accounts are for demonstration only.
