

AI Usage Note

Project: StockFlow, an order fulfillment hub for XYZ | Author: Sumit Meena

Which AI tools I used, and how

I used **Claude Code** (Claude Sonnet 5.5) in the Claude desktop app, working directly in my project folder, as a pair programmer that I directed. **Most of the code was written by the AI.** My part was deciding what to build, checking it against the brief, and shipping it.

- **Design and code:** Claude proposed the stack (React, Express, Prisma/SQLite, JWT login) and generated the data model, API, stock-allocation, delay-alert and courier-suggestion logic, the interface, and demo data.
- **Verification:** Claude wrote 15 unit tests, typechecked and built the app, and ran the whole flow through the API and in a browser (process, overflow move, wrong-item scan, pick, pack, stage, courier handover).
- **Follow-ups:** Git and deployment troubleshooting, packaging the app as one service for hosting, a one-page version of this note, and a script outline for my video.

Moments where I disagreed with or changed an AI suggestion

- **Copying an existing project:** I first asked the AI to copy a public GitHub project and remove the author's name. It declined, because an unlicensed repository is protected by default and removing attribution would infringe it. I agreed and switched to an original build under my own MIT license. Only that project's README summary was seen; none of its code was copied.
- **The first version did not meet the brief:** I compared the AI's first app with the assignment and asked whether it fully matched. The AI's own review said no: it covered stock and picking but lacked priority orders, delay alerts, couriers and labels, packing and staging, a second warehouse, wrong-item checks and an issue log. I had it build all of these rather than explain the gaps away.
- **Roles looked identical:** I noticed that office and warehouse users could open the same pages and asked why the roles existed. The server already blocked office-only actions, but the menu made them look the same, so I had the warehouse menu cut down to the pages that team needs.

My own judgement on top of the AI output

- **Focus:** I chose to follow the six steps in the brief (received, processed, picking, packing, staging, shipping) and to tackle the problems that cost the business money first: missed priority deadlines, unnoticed delays, wrong items shipped, and stock that cannot be found.
- **Simple for a non-technical team:** one warehouse task screen with large buttons, most urgent first, with office-only functions kept away from the floor staff.
- **Trade-offs I accepted:** SQLite so it runs with only Node installed (on a free host its data resets on restart); SKUs are typed or scanned without scanner hardware; demo accounts and sample data are for demonstration only.
- **Verification:** I ran the app and the demo route myself instead of trusting the generated code, and I can explain how stock is reserved, moved, picked and shipped.
